The basic approximation in open channel hydraulics, which is usually a very good one, is that variation along the channel is gradual. One of the most important consequences of this is that the pressure in the water is given by the hydrostatic approximation, that it is proportional to the depth of water above.

Open channels are designed to carry a design discharge in a safe and economical way. For flood control channels the design discharge represents the peak discharge expected to result from a flood event of a specified return period. Normally, the design discharge is obtained from the hydrologic study of upstream watersheds.
